Abstract

Field diffusion programs were conducted at Cape Canaveral, Florida and Vandenberg AFB, California during 1961 and 1962. These programs, nicknamed Ocean Breeze and Dry Gulch respectively, were undertaken to establish quantitative diffusion predictions for use as range safety tools at the missile test ranges. The programs culminated at each range with the installation of an automatic computer-controlled meteorological data acquisition and processing system now in continuous operation at the bases. These systems have been named Weather Information Network Display (WIND) systems.

Volume I describes the diffusion experiments that were conducted as well as summaries of the resulting experimental data. Volume II is devoted to analyses of the data to develop diffusion prediction equations, description of the WIND systems, recommendations for operational use of the prediction equation and WIND systems, and preliminary climatological summaries for each missile test range.

Preface, Volume I

During November 1960, the Air Force Ballistics Systems Division requested the Air Force Cambridge Research Laboratories to undertake an extensive program involving field diffusion experiments and micrometeorological instrumentation at Cape Canaveral, Florida and Vandenberg AFB, California. The motivation for the program arose from planned launches of missiles employing toxic propellants. Range safety procedures that had been developed prior to this time were completely inappropriate for air pollution problems. In fact, air pollution problems in general involved range safety concepts that were unfamiliar to many of the people concerned. The purpose of the effort, then, was twofold:

- (1) To design and conduct diffusion experiments in the field in order to develop quantitative, reliable statements of air pollution hazard or potential at all times.
- (2) To provide the range safety officials and the staff meteorologists with an operationally useful system for describing the state of the atmospheric boundary layer as defined by the parameters of the air pollution problem.

Part of the first objective was undertaken jointly by AFCL and the General Electric Company's Atmospheric Physics Operation Group at Richland, Washington. Accomplishment of this objective has resulted in a large amount of diffusion data which are presented in Volume I. The analyses of these data and the design of a system to use the results of the analyses represent an operationally oriented answer to a specific air pollution problem and are presented as Volume II. Presently, Volume II can be distributed only to agencies with a 'need to know' requirement. It is anticipated that an unrestricted distribution of Volume II will occur sometime during 1965.

Diffusion data and supporting meteorological data are presented for a total of 76 experiments at Cape Canaveral and 109 experiments at Vandenberg AFB. These data significantly implement the store of existing data obtained from field diffusion experiments that would not have been possible without the efforts of many people who gave freely of their time and interest in gathering these data.

The many people who have contributed to the effort are among those acknowledged in the appropriate chapters of this report or are authors of specific chapters. We are happy to take this opportunity to extend our thanks to everyone concerned for their efforts on this problem.

1. INTRODUCTION

Here the various measurements that were made during the field work at Cape Canaveral and Vandenberg AFB will be outlined. These experiments and the resulting data are properly classified as 'engineering information'. For scientists intimately concerned with assessing air pollution hazards, the data are quite useful since they represent a large sample of diffusion data from two geographical locations differing widely in terrain, vegetation, and climate from any other site of similar experimental work. For ease in discussion, the field diffusion efforts have been nicknamed as follows: Project Ocean Breeze for the experiments at Cape Canaveral; Project Dry Gulch for those at Vandenberg AFB.

(Received for publication 18 September 1963)

2. DESIGN OF TRACER EXPERIMENTS

To assess the pollution problem of a potential accident associated with a missile system, one should simulate the modes of toxic releases that are possible, and sufficiently sample the air at various distances and azimuths downwind from the release point so that the exposure levels will be accurately established. It is also necessary to measure the meteorological variables in and about the area of the trajectory of the release so that the relation between these and diffusion parameters obtained from sampling the cloud will be determined. When this dependency is known, the basis for the prediction of exposure levels and cloud widths has been formulated and the micrometeorological system is operational.

Discussions with various people concerned with general air pollution problems at Cape Canaveral and Vandenberg quickly revealed that the majority of conceivable and probable accidents could be characterized by ground-based continuous point sources of pollutant. There was, at that time, considerable data available from continuous point-source diffusion experiments. Notable examples of relatively extensive, sophisticated diffusion experiments are the Prairie Grass data, obtained at O'Neill, Nebraska in 1956,¹ and the Green Glow data, obtained at Richland, Washington in 1959.² Because of the availability of these data, it was necessary only to design experiments that would highlight operationally significant differences, if any, between the various sets of data.

The period of emission chosen for the diffusion experiments was 30 minutes. Very limited knowledge is presently available about actual pollutant emission periods at the missile ranges. It is known that actual pollutant emission periods could vary from a few minutes to a few hours, depending on the total amount of propellant spilled, whether it is spilled into a catch basin and drained or burned off, whether a fuel-oxidizer mixture is present, whether water is mixed with a spill - to cite some of the factors leading to emission period variability. Thus, from the point of view of accident simulation, the choice of a 30-min emission period could be considered somewhat arbitrary; in practice, the diffusion results to be presented can be used with confidence to assess the advisability of any given operation with toxic materials. However in the case of an actual accident, the interpretation of the diffusion results must account for significant differences in emission periods as well as possible effective source heights.

The actual choice of the emission period was made only after consideration of two other aspects of the problem. One was the general scale or scope of the particular problem that was determined to be of the order of 2 to 5 mi for unstable conditions, and 10 to 40 mi for stable conditions. The other was the predominance of an on-shore or sea-breeze circulation during the daylight hours at both sites for practically the entire year. It was desirable to study the sea-breeze situation in

particular, since an 'a priori' range safety rule had been established at both sites that effectively precluded all operations with toxic propellants during on-shore wind conditions. Therefore it was necessary to determine actual turbulent diffusion characteristics under sea breeze conditions as accurately as possible. Since this meant that the most important experiments for operational purposes would be conducted under unstable conditions, an emission period as long as possible was chosen in order to obtain nearly 'steady-state' sampling periods.

The criteria for the operation of the diffusion experiments and the geometry of the sampling grids at Cape Canaveral and Vandenberg were formulated on climatological data of those sites, physical characteristics at those locations, and most important, on the experience from prior tests at Hanford that used the same experimental techniques. The initial design criteria included the following features:

- a. Sampling would be conducted along arcs concentric about the source at radial distances dictated by the scale of the problem.
- b. Where possible, the arcs were to be spaced logarithmically from the source.
- c. The tracer material would be released from a ground-level source.
- d. The period of emission would be 30 min as previously discussed.

In addition, features peculiar to the use of the Hanford Tracer System had to be factored into the design. These were as follows:

- e. Maximum release rate for the dispersal of the tracer was not to exceed 8 kg per hour.
- f. The sample-assaying system employed the Rankin Counter, an automatic zinc sulfide particle detector, which is described in Chapter II. The sample assaying was to be conducted at the Hanford Plant.
- g. Centerline or peak exposures should be at least 100 times the background count to insure the required accuracy in arewise dispersion estimates.
- h. Field samplers would be in operation well before and after the passage of the cloud providing measurements of dosage rather than concentration.

3. CAPE CANAVERAL - OCEAN BREEZE EXPERIMENTS

The Ocean Breeze source point was located between Launch Pads 15 and 16 approximately 350 yd inland from the coastline. The diffusion course consisted of three arcs concentric on the source point at radii of 0.75, 1.5, and 3.0 miles. Samplers were placed at 2° intervals on Arcs 1 and 2, and 1.5° intervals on Arc 3. Arcs 1 and 2 extended from 152° through south to 340° azimuth bearing on the source point; Arc 3 from 152° through south to 236.5° azimuth bearing on the source point. A schematic diagram of the Ocean Breeze sampling course is shown in Figure 1. (An aerial photograph of Cape Canaveral is shown in Figure 2 which also includes the sampling arc service roads.) It should be noted that the orientation of

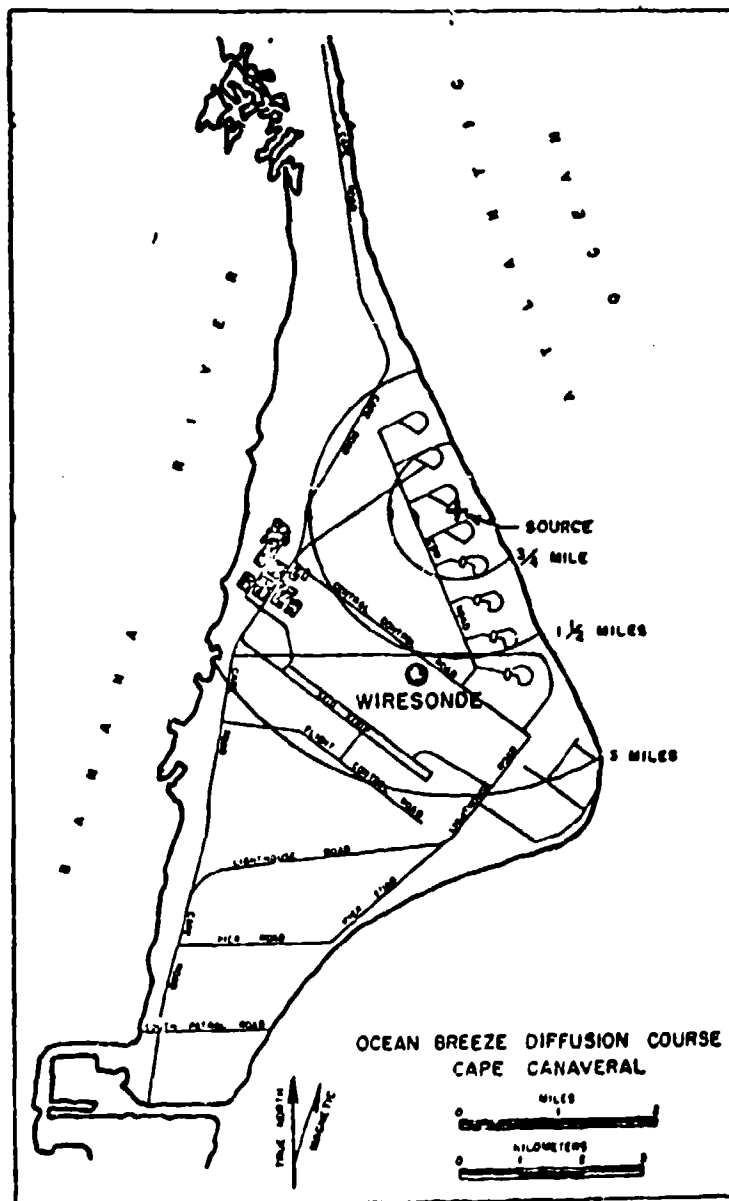

Figure 1. Ocean Breeze Diffusion Course Layout

Figure 2. Aerial Photograph of Cape Canaveral Showing Sampling Arc
Service Roads

the course was such that Arc 3 could only be used with northerly winds, a wind direction which occurs fairly frequently during the winter at Canaveral. Most of the Ocean Breeze experiments were conducted during sea-breeze conditions, or under easterly winds. Therefore, most of these data are restricted to Arcs 1 and 2.

The terrain at Canaveral consists generally of rolling sand dunes 10- to 20-ft high. Much of the diffusion course was covered with dense palmetto growth and brushwood. The palmetto varies in height from about 2 to 5 ft; the brushwood from about 7 to 14 feet. (See Figure 3 for a typical photograph of Canaveral vegetation.) Because of the dense vegetation, all filters were placed at 15 ft above local ground level. To enable a rough check on the degree of vertical mixing within the cleared areas along each arc, an additional 15 filters each were installed at 5-ft heights on Arcs 1 and 2 at azimuth positions of 240°, 246°, 252°, 258°, 264°, 270°, 276°, 282°, 288°, 294°, 300°, 306°, 312°, 318°, and 324°. A summary of comparison between observed 5- and 15-ft concentrations is presented in Chapter II.

Figure 3. Palmetto and Brush Growth Typical of Much of Cape Canaveral Vegetation

Preparation of the diffusion course was accomplished by a local company under contract to the Air Force Missile Test Center (AFMTC), according to specifications furnished by AFMTC. This work included clearing out the vegetation for the source

point and sampling arcs, surveying the positions of the filters and source point, installing the sampling posts, providing electrical power at the source point, and constructing service roads behind each sampling arc. Pan-American Airways, Inc., the AFMTC range contractor, provided the hose, vacuum pumps, gasoline engines, and hardware necessary to instrument each sampling position. Pan-American also provided the radio-equipped trucks and personnel necessary to operate the diffusion course.

Technical supervision of the diffusion experiments was provided by personnel of the Atmospheric Physics Operation, General Electric Company, Richland, Washington. This consisted of training the field crew, scheduling each diffusion experiment within the framework of other activities and favorable wind and stability conditions at Canaveral, and maintaining a close check for anomalies in the operation of the generators and samplers. General Electric also furnished all the filters and tracer material necessary for the experiments, and provided AFCRL with a tabulation of the diffusion data resulting from each experiment.

4. VANDENBERG AFB - DRY GULCH EXPERIMENTS

The terrain at Vandenberg is extremely complex, about as far removed from an ideal flat plane as one could imagine. Significant terrain features consist of a broad mesa 200 to 300 ft in elevation sloping to the west with a 40- to 60-ft bluff at the coastline and rugged foot-hills and ridges inland. The mesa is cut up by several sharp, fairly deep ravines and has well-defined valley systems at its northern and southern edges. Both valley systems are oriented roughly along WNW to ESE lines; the northernmost valley (San Antonio Valley) being fairly narrow with relatively steep sides, the southernmost valley (Lompoc or Santa Ynez Valley) being quite broad with gently sloping sides. Vegetation at Vandenberg generally consists of grasses to a height of 1 to 2 ft, occasional clumps of brush 5- to 6-ft high and an occasional line of eucalyptus trees to heights of 50 to 80 feet. (See Figures 4, 5 and 6 for typical photographs of Vandenberg terrain and vegetation features.)

The complexity of the terrain at Vandenberg led us to design two Dry Gulch diffusion courses; one up on the mesa, and one along the Lompoc Valley line, both courses being oriented to sample the predominant on-shore sea-breeze circulation. The B-course laid out on the mesa had a source point about 2600-yd inland from the coastline. Two sampling arcs, B-1 and B-2, were surveyed concentric on the source point at radii of 1.43 and 3.52 mi (2301 and 5665 m). Samplers were placed at 2° intervals on Arc B-1 which ran from 87° azimuth through east to 171°. Samplers were placed at 1° intervals on Arc B-2 which ran from 85° azimuth through east to 171°. (See Figure 7).

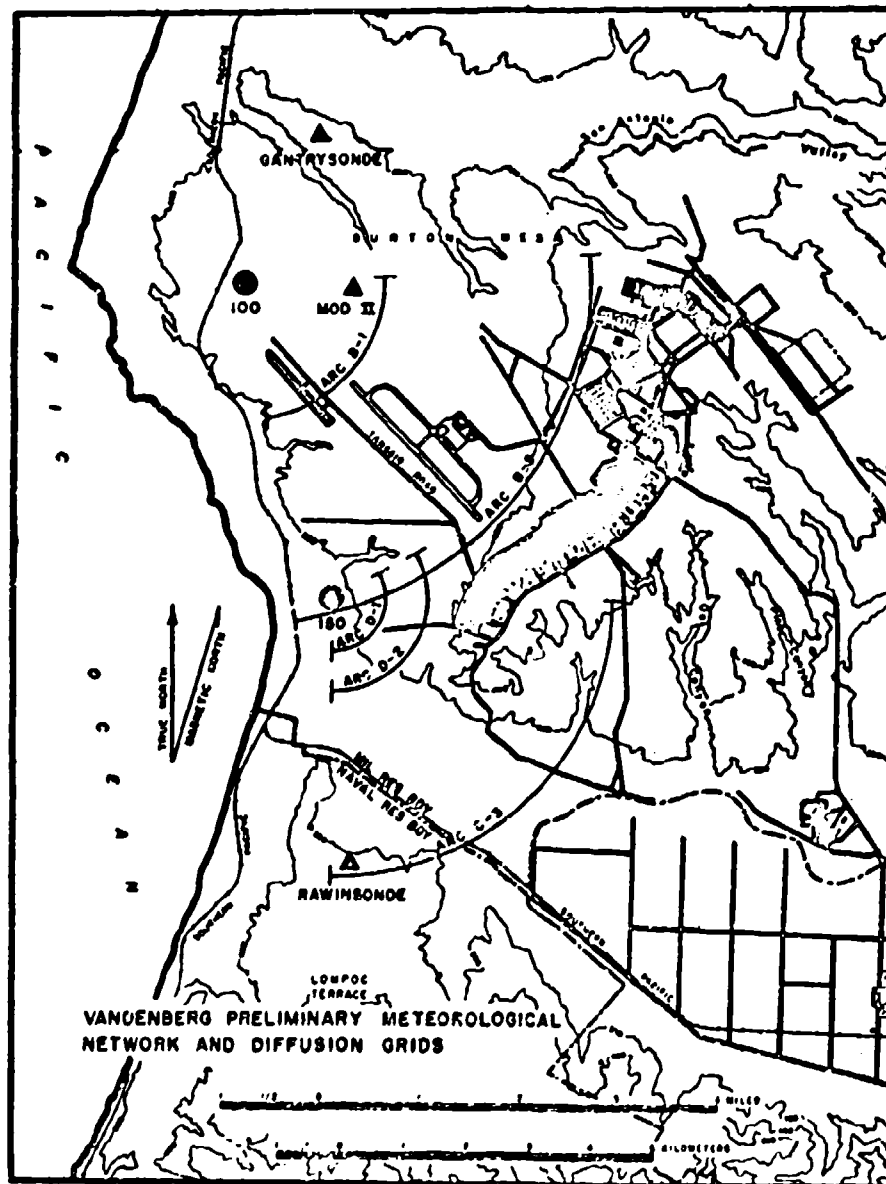

Figure 7. Dry Gulch Diffusion Courses

The D-course laid out along the southern edge of the mesa and up the Lompoc Valley had a source point about 1100-yd inland from the coastline. Three sampling arcs, D-1, D-2, and D-3, were surveyed concentric on the source point at radii of 0.53, 0.93, and 2.93 mi (853, 1500, and 4715 m). Arcs D-1 and D-2 extended from 60° azimuth from the source point to 180°. Arc D-3 extended from 110° to 180° for the first two series of experiments by which time it was discovered that the mean wind direction frequently did not follow terrain features along the valley, but instead followed fairly straight lines across the hills on the north side of the valley. Accordingly, Arc D-3 was extended 20° on the north to 90° for the third and final series of Dry Gulch experiments. Arcs D-1 and D-2 had 2° sampler spacing; Arc D-3, 1° sampler spacing. All sampler heights for Dry Gulch were 1.5 m above local ground level.

Preparation of the diffusion courses consisted of the same activities as outlined for Ocean Breeze. It was accomplished by The Martin Company, Vandenberg, under contract to the Air Force Ballistics Systems Division according to AFCRL specifications. General Electric Company personnel performed the same activities for Dry Gulch as they did for Ocean Breeze.

5. METEOROLOGICAL SUPPORT

Supporting meteorological measurements were taken for each Ocean Breeze experiment by personnel of Pan-American's Cape Weather Station. Wind speed and direction were measured by Belfort Instrument Company's Type M located at the source point and exposed at a height of 12 ft above terrain. (See Figure 8 for a photograph of the Ocean Breeze source point.) Recording was on strip charts that were driven at the rate of 3 in./min for a nominal 60-min period beginning with the tracer emission period. Computations of mean wind speed and the standard deviation of wind direction fluctuations were then made for the 30-min period corresponding to the emission period or, in some cases, a 48-min period starting with the emission period. These data are tabulated in Chapter III.

Temperature profile information was derived from three wiresonde measurements of temperature from the surface to 500 ft read at 50-ft intervals on each ascent and descent of wiresonde captive balloon. The wiresondes were begun about 15 min prior to the beginning of emission and usually took about 45 min for completion. The wiresondes were taken at the Cape Weather Station a few hundred feet downwind from Arc 2 at an azimuth bearing from the source point of about 196°. (See Figure 1.) Mean vertical temperature differences computed from these data are tabulated in Chapter III. It is worthwhile to note here, however, that these data

are more subject to error than all other data obtained during Ocean Breeze simply because of the inherent limitations of the rawinsonde observational system.

Detachment 11, 4th Weather Group, Air Weather Service, Patrick AFB provided support to the Ocean Breeze activities by furnishing copies of standard synoptic data for Patrick AFB and Cape Canaveral. These data consist of the WBAN 10A and 10B surface observation forms, copies of the surface synoptic maps analyzed for the area, and rawinsonde data collected from Cape Canaveral by Pan American Airways, Inc. The Weather Detachment also provided wind direction forecasts in direct support of scheduling each Ocean Breeze diffusion experiment. Since these data are standard synoptic data usually readily available to interested parties, they are not presented here. The rawinsonde data, however, are presented.

Supporting meteorological measurements were made for each Dry Gulch experiment by personnel of Detachment 3, 3rd Weather Wing, Air Weather Service. Wind speed and direction were recorded by Belfort Type M wind sets exposed at 12 ft above terrain at each source point. Recording was at the rate of 3 in./min as at Ocean Breeze and the same type of data reduction was accomplished. (See Chapter III.)

Temperature differences for the first 29 Dry Gulch experiments were obtained by 'gantrysonde', a jerry-rigged device utilizing rawinsonde instruments mounted on an Atlas gantry. Since this was not a particularly trustworthy method of obtaining temperature difference data, the 'gantrysondes' were replaced by rawinsondes. Location of the rawinsonde and 'gantrysonde' sites is shown in Figure 7. The mean vertical temperature difference data obtained from these observations are presented in Chapter III.

Between the first and second series of Dry Gulch experiments, it was decided to augment the rawinsonde measurements by measuring the temperature difference between 6 and 54 ft on a fixed tower known as the MOD-II site. (See Figure 7.) These measurements were obtained by recording the temperature difference indicated by thermocouple junctions exposed at these heights in wind or naturally-ventilated radiation shields designed, built, and loaned by Dr. William Clayton, Agricultural & Mechanical College of Texas, College Station, Texas.

Between the second and third series of Dry Gulch experiments, one more observational site of vertical temperature difference was established, using 6-junction thermopiles in Beckman-Whitley aspirated shields at heights of 6 and 54 feet. Recording was on Rustak recorders. The site for these observations was near the source point for the D-course. Tabulation of mean vertical temperature differences obtained from these two charts for the Dry Gulch experiments is presented in Chapter III.

In addition to the meteorological support provided by Detachment 3, the U. S. Weather Bureau rawinsonde station at Point Arguello, a support group at the Pacific

Missile Range, made special releases and detailed computations of the wind and temperature profiles up to 700 mb for most of the Dry Gulch experiments. For those experiments that coincided with their regular observation time, the regular rawinsonde observation was used. These rawinsonde data are tabulated in Chapter III. It should be noted, however, that the rawinsonde site is about 8-mi south of and 200-ft higher than the wiresonde site. Vandenberg local circulation patterns are characterized by frequent occurrence of a marine inversion layer, a phenomenon which has possible important effects on air pollution levels. For a discussion of which effects were observed, refer to Volume II, Chapter III of this report.

One other set of meteorological observations made for both Ocean Breeze and Dry Gulch should be mentioned. These consisted of battery-operated Belfort Instrument Company Type C's which were installed at 12 sites at Canaveral and 18 sites at Vandenberg for the purpose of obtaining horizontal wind-trajectory information. These instruments were especially built for these programs, but proved to be unsuccessful. The primary reason for their failure was corrosion of the speed and direction commutators when exposed to high concentrations of sea salt, a problem anticipated but not fully appreciated prior to instrument installation. Personnel of Detachment 3, Vandenberg were particularly industrious and ingenious in maintaining and modifying the Type C wind sets in the field, but the resulting data are deemed insufficient in both quantity and quality to merit tabulation.

6. EXPERIMENTAL TECHNIQUES FOR TRACER EXPERIMENTS

The general method in conducting a dispersion experiment is to release a tracer material into the air at a known and constant rate, and sample the material at various distances and azimuths downwind. The results must be quantitative so that careful design of sampler and assaying systems is essential. In addition, the analysis planned for the data must be at least partially determined in advance so that the final confidence requirements on the data can be factored into each step in the conduct of the experiment.

The atmospheric tracer material used during these experiments was the fluorescent pigment, zinc sulfide, U. S. Radium Corporation designation No. 2210. It is a very fine particulate which fluoresces green under ultraviolet light. The particle size distribution is nearly log-normal with a geometric mean of 2.5 μ and a standard deviation of the logarithms of the diameter of 0.70. The material specific gravity is 4.1.

The fluorescent powder is mixed with a surface active agent, sodium lauryl sulfate, in the ratio of 2 g detergent per kg of pigment. A small amount of water, about 1/2 gal, is added to the dry material and thoroughly mixed with a paint shaker.

Glass beads are added to enhance mixing. The slurry is then transferred to a large formulation tank, where it is further mixed with additional water for at least 20 min before release through the dispenser. The recirculation rate, prior to and during emission, is 4800 gal per hour. Homogeneity of the formulation is checked by drawing samples directly from the intake line of the dispensers during generation.

The fluorescent pigment slurry is dispensed through two standard Todd Insecticidal Fog Applicators (TIFA). The TIFA, shown in Figure 8, is an aerosol fog generator which consists of four primary components: an air blower, which delivers 160 cfm to the atomizer cup, used to atomize the liquid carrier; a combustion chamber, used to heat the air from the blower and aid atomization and evaporation of the carrier; a formulation pump to supply the formulation to the atomizer cup under pressure; and a 7.5 hp gasoline engine to drive the blower and the pump and, also, to supply a continuous electric spark to fire the combustion chamber.

Figure 8. Ocean Breeze Source Point Showing the Todd Insecticidal Fog Applicators Emitting Pigment. Belfort Type M Wind Set is Seen in Background.

The generators are operated in pairs, side by side, with a common formulation tank to obtain release rates up to 8 kg per hour. The dispensing rate is varied by adjusting the formulation pressure or by adjusting the droplet size selector or a

combination of both. (Once set, the dispensing rate is essentially constant.) It was determined that a volumetric generation rate of 20 gal per hour and a blower air temperature of 750°F would produce a spray which essentially evaporates within a few feet of the nozzle. To minimize losses on vegetation close to the source, the nozzles of the two dispensers were pointed upward at an angle of about 30°, giving an effective source height of 2 to 3 m above ground. The nozzles of the two dispensers were pointed inward to make an angle of about 40° with the centerline of the sampling grid producing effectively a single source.

The generation rate was set prior to each release and was not altered after generation was started. The actual amount of pigment emitted during each run was computed by subtracting the amount of formulation remaining in the tank at the end of the generation period from the total formulation in the tank at the beginning of the generation period.

The primary sampler used in the Cape Canaveral and Vandenberg AFB experiments was a membrane filter inserted in a disposable polyethylene holder. Samples collected on a filter were bulk samples intended to collect all pigment passing through the intake zone during a given run. Figure 9 shows that the sampler unit consists of five parts: The base contains a cavity in which a cylindrical roll of creped-paper filter backing is inserted; a molecular membrane filter (Membrane Filter, 47 mm diameter, Type AM-1 of Gelman Instrument Co., Chelsea, Michigan) is placed on the plane circular surface formed by the base and the filter backing; the retaining ring pinches the periphery of the filter tightly against the base, while the circular area of 1-5/8-inch diameter that is still exposed is supported by the porous creped backing; the dust cap merely protects the filter surface both prior to and subsequent to sampler exposure. Vacuum is applied at the ribbed nozzle of the base and the dust cap is removed during field operation. Each filter holder was used only once; thus, there was a complete new set of sampling units for each field test, eliminating any possibility of contamination from the sampling assembly.

Figure 9. Blow-up of Membrane Filter Sampler Unit

The basic vacuum system used throughout consisted of a Gast-Model 2585V, heavy duty, vane-type vacuum pump driven by a Clinton-Series 290, Model TBA, air-cooled, 4-cy, 1-cylinder, gasoline engine shown in Figure 10. Each unit would provide 5 cfm of air flow at critical flow and would operate for at least 4 hr without refueling. Where lower volumetric flow rates were adequate, the samplers were manifolded to the vacuum pump by connecting them with 1-in. vacuum hose.

Figure 10. Photograph of Vacuum System Used with Sampler Units

It is important to determine the rate of air flow through the filter if the exposure data are to be accurate. Consequently, all the orifices used in the Ocean Breeze and Dry Gulch Programs were individually calibrated, taking into account the small reduction in flow due to the pressure drop across the filter. The approximate size of the orifices required for critical flow for each arc was first determined from the anticipated source strength, the estimated dilution of material as determined from previous experiments, and the range of mass values that the counting equipment could accurately detect. Once the desired flow rate for each arc was determined, the individually calibrated orifices were selectively grouped for each arc. Because of the small range of flow rates on any one arc, it was possible to use the mean value for the entire arc. The resulting error contributed less than 1 per cent of the overall standard error, which is listed in the table of results, Chapter II.

The mean values of the flow rate are given in Table I.

TABLE 1. Mean flow rates for Ocean Breeze and Dry Gulch experiments

Ocean Breeze		Dry Gulch

		D-2	0.001864
3	0.002048	D-3	0.001864

7. DESCRIPTIVE SUMMARY OF EXPERIMENTS

An attempt was made to conduct diffusion experiments which would sample significant seasonal differences in local circulation patterns at Canaveral and Vandenberg. For Canaveral, experiments were conducted during the summer and winter seasons; summer because of the high frequency of occurrence of sea breezes; winter because of fairly frequent cold frontal passages which occurred with northerly winds and, it was thought, possibly frequent very unstable conditions. For Vandenberg, experiments were conducted within and during the absence of the marine layer with a strong capping inversion. These were also essentially summer and winter experiments.

The purpose of the experiments was, again, to provide data for developing and testing diffusion prediction equations for operational use at Canaveral and Vandenberg. Concurrent with the field diffusion work, AFCL was actively engaged in obtaining an automatic meteorological data observation and processing system to be installed at each base. This system continually provides as output, among other things, solutions to the diffusion prediction equation developed for the missile base. (See Volume II, Chapters II and III.) Therefore, in an attempt to test the system output against actual diffusion test data, a third series of experiments was conducted at both bases.

There were 76 diffusion experiments conducted during Ocean Breeze over approximately a 12-mo period; 23 were conducted between 15 May and 14 June 1961; 27 between 11 January and 3 February 1962; 26 between 10 March and 31 March 1962. There were 109 diffusion experiments conducted during Dry Gulch; 52 were conducted between 12 June and 3 August 1961 (24 on B, 25 on D, and 3 on course B with Arc D-3 also activated); 27 between 5 February and 29 March 1962 (13 on B, 14 on D); 30 between 31 May and 29 June 1962 (17 on B, 13 on D).

The diffusion experiments are summarized in Table 2 according to a stability classification scheme loosely defined as very stable, moderately stable, moderately unstable, and very unstable. To classify each experiment, values of the mean temperature difference between 6 and 54 ft, denoted by ΔT , were used. Numerical limits of ΔT for the various categories are indicated in the Table. The primary value of Table 2 is to emphasize the very high frequency of the experiments that are classified as moderately unstable. This, of course, is a direct result of orienting the diffusion courses to study on-shore circulation patterns. Stable conditions occur very rarely with on-shore winds at either base, the most common stable situation being nearly calm conditions or winds drifting air very slowly out to sea. Neither of these latter conditions could be studied with the diffusion courses, although this is obviously of little concern to the operational problem of scheduling potentially hazardous air pollution incidents. Under calm conditions, one simply does not schedule a potentially hazardous activity, regardless of the stability. With persistent off-shore winds, no air pollution hazard exists to personnel working at the missile bases.

The strong bias toward unstable conditions is somewhat undesirable for the purpose of developing diffusion prediction equations of general applicability for a wide range of low-level stabilities. The solution to this problem that has been adopted at both Canaveral and Vandenberg may be found in Volume II, Chapter I.

Acknowledgments

We gratefully acknowledge the help of the many people whose diligent and enthusiastic efforts made the design and conduct of these experiments possible.

Morton L. Barad, AFCRL, has participated actively in many long discussions of the overall effort with the authors. Max F. Scoggins, General Electric Company, personally checked the sampling equipment installations and trained the field crews in the necessary experimental techniques for both Ocean Breeze and Dry Gulch. Charles Simpson, General Electric Company, was the test conductor for all Ocean Breeze experiments. Charles Elderkin, General Electric Company, was the test conductor for all Dry Gulch experiments.

1A. Colonel Robert L. Miller, at first a member of Detachment 11 at Patrick AFB and later Detachment 54 at Hanscom Field, 4th Weather Group, Air Weather Service, was the AFMTC Project Officer for Ocean Breeze from January 1961 to January 1962 and AFCRL's representative for the last two series of Ocean Breeze experiments. Richard Whelpley, Pan-American Airways, Inc., was outstanding in ensuring the successful and accurate completion of the Ocean Breeze diffusion course. David Dunkle, Pan-American Airways, Inc., managed the general logistical plans preparing for Ocean Breeze including ordering and preparing for use the field diffusion equipment. David Newton, Manager, Range Operations, Pan-American Airways, Inc., almost single-handedly took care of our day-to-day scheduling, personnel, vehicle, and general logistic problems.

Major John H. Taylor, AFCRL, was the AFCRL Project Officer for all the Dry Gulch experiments. Major W. Leon Dotson, Detachment 3, 3rd Weather Wing, Vandenberg, organized the meteorological support services required by the Dry

Gulch program and, in addition, served as our point of contact on many daily logistical problems. M/Sgt. Granville Frichette and M/Sgt. Howard Cooke, Detachment 3, 3rd Weather Wing, were outstanding in maintaining all the meteorological support equipment used during Dry Gulch. William Selby, The Martin Company, supervised the preparation of the Dry Gulch diffusion courses. Harvey Hines, The Martin Company, supervisor of the Dry Gulch field crew, was extremely helpful in solving many of our daily scheduling, personnel, and vehicle problems.

The deep personal interest in the objectives of the effort displayed by all these people, and many others too numerous to mention, has been invaluable.

1. INTRODUCTION

The diffusion data obtained during the experiments described in Chapter I were reduced by personnel of the General Electric Company at Richland, Washington. The purpose of this chapter is to present summaries of these data. Field notes taken during the experiments which in many cases may be used to explain questionable data are also presented.

2. DESCRIPTION OF ASSAYING TECHNIQUE

All bulk samples of tracer collected during Projects Ocean Breeze and Dry Gulch were forwarded to Hanford for assaying in a Rankin counter. This device (Figure 1) permits quantitative detection of the fluorescing tracer on the standard filter.

In the partially disassembled Rankin counter shown at the left in Figure 1, it can be seen that 12 complete field samples can be inserted simultaneously in the turntable of the counting pig. The only processing that must be done to a field filter before its insertion in the counter is the removal of the dust cap.

Figure 1. The Rankin Counter. The instrument partially disassembled is shown at left, the assembled unit at right.

The filter is rotated to the counting position directly under a Dumont 6292 multiplier phototube. Figure 2 schematically illustrates a filter in counting position. A 200-microcurie plutonium source, in the shape of an annulus about the base of the phototube, bombards the zinc sulfide tracer with alpha particles. The resulting scintillations are viewed by the phototube, amplified, and tallied on a scaler.

The Gelman AM-1 membrane filter used in the sampler retains the bulk of sampled tracer particles at its surface. This surface retention facilitates the excitation of the sampled tracer by the bombarding alpha particles.

Design of the counting pig permits the counter operator to insert and remove filters from the turntable at the same time a filter is being counted under the phototube. This procedure resulted in considerable saving of time considering the large number of filters (roughly 40,000) assayed during Ocean Breeze and Dry Gulch.

The scaler count rate (C) is converted to the mass (M) of tracer by means of the relationship

$$\log_{10} M = 0.95211 \log_{10} C - 9.07924$$

where C is in counts per minute. The background counting rate is about 5 counts

Figure 2. Schematic illustration of filter in counting position in Rankin counter.

per min - the equivalent of 4×10^{-9} g of tracer. The calibration has been found to hold for masses as high as 6×10^{-4} grams.

3. OCEAN BREEZE DIFFUSION DATA

Table 1 contains values of dosage in gm sec m^{-3} as measured at a height of 15 ft above the ground for each of three sampling arcs employed in the Ocean Breeze program, as well as values of the relative standard error, which is defined as the standard deviation of repeat determinations of mass on a given filter as a percentage of the mass collected.

For convenience, the data in Table 1 are presented in the form of a computer listing. The first word is an identification word; the second contains the exposure as measured at an azimuth given in the first word. The appropriate relative standard error is given in the third word. The fourth, fifth, sixth, and seventh words contain the dosage and relative error at the next sampler position in a clockwise rotation.

In the first word, the first digit denotes the arc; the second, third, and fourth digits specify the number of the experiment; the sixth, always a 9, denotes the 15-ft level; the seventh, eighth, ninth, and tenth digits denote the azimuth of the sampler. An entry of 2040 in the last four digits of the first word indicates an azimuth of 204.0° . However, since the tenth digit specifies the number of quarter-degrees, an entry of 2042 in the last four digits indicates an azimuth of 204.5° . This device was adopted to accommodate the half-degree spacings on Arc 3.

Table 2 contains the values of exposure in gm sec m^{-3} as measured at heights of 5 ft above the ground and is interpreted in the same manner as the data in Table 1, except that the sixth digit of the identification word is always an 8 to denote the 5-ft level.

An asterisk preceding an 'exposure' word indicates that the value reported could possibly be in error. Errors arise because of such reported mishaps as dust on filters, spilt filters, engine troubles, filter caps left on, and so forth. Table 3 summarizes all notes taken at the site during the testing and in the analysis of the samples in the Hanford laboratory. These notes correspond to the asterisks printed with the exposure data. It will be noted that light dust was found on many of the samples. This resulted mainly from the fact that the sampling time was necessarily long because of light winds associated with many of the tests. This problem was critically examined during the Green Glow program and correction factors were applied to compensate for this effect. The dust on the filters at Cape Canaveral was, however, so light that the effect of its presence did not significantly affect the exposure values that are given.

Table 4 presents the arcwise integrated exposures and the standard deviation of arcwise mass distributions for Ocean Breeze. The arcwise integrated exposure is defined as the product of the exposure and sampler spacing summed over the entire arc, or $AIE = \sum E_y \Delta y$ (over all y) where y denotes the arc position and Δy is the sampler spacing.

Table 5 lists the periods during which fluorescent particles were emitted for the diffusion experiments at Cape Canaveral, and also the total amounts (Q), in kilograms, of tracer material emitted. The length of the period of emission was always 30 minutes.

4. RELATIONSHIP BETWEEN 5- AND 15-FT OCEAN BREEZE EXPOSURE DATA

Secondary level samplers, placed 5 ft high and spaced 6° apart between 240° and 330° azimuth on Arcs 1 and 2, were in the tracer plume on 39 field tests, of which only 9 were run at night. The ratio of exposure at 5 ft to exposure at 15 ft was calculated for each data point, and will be designated R in the following discussion.

The range of R found was 0.1 to 11.5 for day runs and 0.1 to 4.3 for night runs. After averaging all observations made at each azimuth, the range decreased to 0.1 to 2.5 for day runs and 0.1 to 4.3 for night runs. Values of R greater than approximately 1.5 or less than about 0.5 almost invariably occurred at the edge of the plume, with exposures two to five orders of magnitude less than the peak exposures. Two exceptions were found; one during a day run ($R = 8.5$) and one during a night run ($R = 4.3$). Both exceptions were at the peak, and no explanation seems satisfactory for these two oddities.

The mean of R for all day runs was 1.0; for all night runs, 0.9. The overall average R for all runs, all azimuths, and all arcs was 1.0. The variance of R was 0.33 for day runs; 0.48 for night runs. The frequency distributions for day runs were positively skewed; for night runs, slightly negatively skewed. (See Figures 3 and 4.)

Seasonal and vegetational effects were examined, but little significance could be attached to the variations observed. In general, day runs showed no seasonal variation, but a slight dependence on vegetation was indicated, R being about 20 per cent less when surrounded by vegetation more than 5 ft high than when surrounded by vegetation less than 5 ft high. Night runs, however, showed no vegetation dependence; a slight variation with season appeared, R during the summer being about 10 per cent less than that during the winter.

Figure 3. Frequency distribution of ratio of 5- to 15-ft exposure values, Ocean Breeze daytime runs.

Figure 4. Frequency distribution of ratio of 5- to 15-ft exposure values, Ocean Breeze nighttime runs.

5. DRY GULCH DIFFUSION DATA

The exposure data for the Dry Gulch experiments are presented in Table 6 in the same basic format as the Ocean Breeze data. However, because of the two grids used at Vandenberg, it was necessary to denote the sampling arcs as follows: 1 - the first arc on the B Course at a radial distance from the B source point of 1.43 mi, 2 - the second B Course arc at a distance of 3.52 mi, 7 - the first D Course arc at 0.53-mi distance from the D source point, 8 - the second D Course arc at 0.93 mi, and 9 - the third D Course arc at 2.93 mi radial distance. It should be noted that considerable editing of the original data was necessary before the tabulated Vandenberg results could be obtained. This editing was necessary for several reasons. First, sampling equipment failure recorded by the field crew during the tests sometimes produced incorrect data. Equipment failure included engines stopping during the test, lack of necessary pressure differential to produce critical flow,

and damage to filter samples. Dust and carbon collection on some filters, causing a reduction in tracer detection, was also noted when the samples were assayed. During run 57, due to the highest wind of any of the tests, so many adjacent filters on Arcs 7 and 8 were dust laden that no attempt could be made to adjust them. All other erroneous data resulting from sampling equipment failure were replaced with values interpolated between the surrounding correct data.

Second, unusually low dosages were measured at a few sampling positions where sampling was seriously obstructed by terrain or vegetation. These cases occurred where samplers sat at the bottom of deep ravines not characteristic of the general terrain and where samplers fell within or just behind one of the few groups of trees that were not characteristic of the general vegetative cover. In addition to shielding the samples from the plume, these areas often trapped the engine exhaust producing a collection of carbon on the filters that reduced the tracer detection still further. Serious dosage reduction of this sort necessitated editing of data for several of the tests from the following sampling positions: 8-132, 8-134, 8-136, and 9-119, located in deep gullies and 2-099, 2-102, and 9-138 located behind trees. These data were replaced with interpolations between the surrounding representative samples. Many other dosage measurements were considered valid where samplers were partially shielded by the rough terrain features generally found over considerable areas at Vandenberg.

Data were corrected from six sampling positions at 2-133 through 2-138 in the landing strip approach zone where small orifices had to be used during the first series of 52 tests. None of the engine and vacuum pump assemblies could be placed in this area and it was necessary to reach these sampling positions with long hoses from pumps situated outside the approach zone. Flow through the hoses produced a pressure drop which would have been too large to allow critical flow through the $0.001864 \text{ m}^3/\text{sec}$ orifices used on the rest of the arc. Consequently, critical orifices giving half this flow rate were used at these six sampling positions and the counts for the samples taken there were doubled. This allowed the larger flow rate to be used for the entire arc in data reduction and a change in the computer data reduction program was avoided.

The edge of the plume extended beyond the limits of the sampling course on one or more arcs during several tests. In ten of these cases, it was possible to confidently extrapolate with the addition of no more than three data points thus extending the crosswind distribution to near background counts. This was done only when the shape of the extended crosswind distribution tail was clearly established by the valid samples taken near the end of the arc or by the shape of the crosswind distributions contained within the sampling grid on the other arcs. This editing provided better estimates of the crosswind variance in these ten cases.

Because of the intensive testing at Vandenberg with often two and as many as three tests in a day, the accumulation of tracer material deposited on the ground and its continual re-entrainment during the subsequent tests led to anomalous sampling. In most cases, the magnitude of this field contamination was low enough to be comparable only with those dosages at the edge of the plume. This led to a very small average value of field background which was factored into the data reduction and which had an insignificant effect on the dosage calculation. However, when the contamination was found at the tail of the crosswind distribution, it could possibly alter the calculation of the crosswind variance of the plume if not excluded. To combat the contamination problem, an attempt to minimize the effect was made by scheduling the diffusion tests with at least two hours from the end of one experiment until the beginning of the next to allow the wind to 'clear off' the course and reduce the particle pickup to a low level. Also, in editing the data, the anomalous counts were removed when the contamination was identified by noting the path of previous plumes, where contamination would be most likely, and by accounting for particular areas that were found to be recurrent sources of contamination. Also, plotting crosswind distributions and comparing them from one arc to another aided in identifying and eliminating contamination samples.

There were 17 cases of data obviously erroneous in which the reason for the error was unknown. These could possibly be accounted for by undetected faulty equipment, such as a plugged orifice which would restrict the flow, but would offer no visible evidence of improper operation. The sampling position at 7-148 evidently experienced some undetected equipment failure such as this during the first phase of the Vandenberg experiments; in almost every instance where the plume passed that position, a suspiciously low dosage was measured. The lack of experience of the field crews during the first few tests could also account for some of these unexplained erroneous values.

Whenever observed data were changed because of any of the reasons mentioned above, an asterisk appears in front of the data point in the table of dosages, indicating a notation was made concerning that value. Many additional asterisks appear indicating notes where no change in the data was necessary. Such notes concern sampling equipment adjustment where adequate sampling was not interrupted, detection and correction of equipment failures before or after plume passage where sampling of the plume was not affected, light dust or smoke on the filters that did not reduce the count noticeably, cases where the filter was recounted and the second count was listed, and one case where a second sample was collected at sampling position 7-122 during the last two phases of the Vandenberg test series. This sample was taken at the top of a small hill just ahead of the original sample to determine if the hill altered the dosage measured at this point. There was often a factor of

two between the counts at these two samples, but the original sample usually fit the crosswind distribution as well as the second sample and the original sample was used in all cases.

For all those instances where interpolated or extrapolated estimates were used, a list of the notes pertaining to these data points is given in Table 7.

The arcwise integrated exposures and the standard deviation of arcwise mass distributions for the Dry Gulch experiments are presented in Table 8. Emission period data and total amounts of tracer emitted are listed in Table 9.

TABLE 1. Ocean Breeze exposure data (gm sec m⁻³) and relative standard error of data (%) for 15-ft sampling heights. (See text for explanation of data format.)

TABLE 3. Summary of field and laboratory notes for the Ocean Breeze experiments. Position denotes arc and azimuth location of sampler

FIFTEEN FOOT SAMPLE HEIGHTS

<u>Run</u>	<u>Position</u>	<u>Note</u>
1	1-228	Sample dropped on ground
	1-230	Engine changed out during test
	1-242	Filter split
	1-246	Filter dropped
	2-222 to 2-228	Engines out about 5 minutes during test
	2-242	Engine out 2 minutes during test
2	2-244	Filter not properly seated in holder
	1-230	Engine out 5 minutes during test
	2-230	Engine out 2 minutes during test
	2-234	Engine out 5 minutes during test
3	2-206 through 2-228	Heavy ground fog
6	2-294	Data correct, troubles encountered prior to test
10	2-184	Engine dead at end of test - still warm
11	2-204	Light rain after 1945 H
	2-212 through 2-232	Light rain after 1945 H
	3-216	Sample missing, data interpolated
13	1-224 through 1-252	Spray painting near samplers, paint tested and found not to affect these data
14	2-222 and 2-230	Engines dead, values interpolated
15	2-298	Small bird-peck hole in filter
16	1-256	Small bird-peck hole in filter
19	1-272	Bird observed perched on sampler
20	2-248	Light intermittent rain during test
	2-258	Filter missing, value interpolated
	2-276 and 2-278	Heavy rain shower at 1255 H
	2-294 and 2-296	Light rain shower at 1216 H
	2-318	Sample dropped on ground
	3-161	Split in filter
24	2-160 through 2-174	Light dust on filter
25	3-161 through 3-173	Light dust on filter
26	2-152 through 2-170	Light dust on filter
	3-152 through 3-168	Light dust on filter
27	2-178 through 2-186	Very light dust on filter
	3-174	Light carbon on filter
	3-183	Filter touched with finger
28	1-182 through 1-188	Light carbon on filter
	2-182 through 2-186	Light carbon on filter
29	1-176	Data correct, suspicious sample recounted
30	3-159 through 3-188	Light carbon on filter
32	2-182	Data correct, suspicious sample recounted
35	1-254 and 1-258	Data correct, suspicious sample recounted
37	1-254	Filter touched with finger
38	1-256	Data correct, suspicious data recounted
	1-282	Filter not completely seated in sampler
39	1-194	Data correct, suspicious data recounted
	2-190	Engine dead, data interpolated
	2-200	Heavy carbon, data interpolated
	2-242	Engine dead, data interpolated
41	3-164	Engine dead, data interpolated
42	1-194	Data correct, suspicious sample recounted
	1-193 through 1-210	Dust in vicinity, did not affect samples
	2-200	Data correct, suspicious sample recounted
	3-159 through 3-162	Smoke in vicinity, did not affect samples

TABLE 3 (contd)

Run	Position	Note
43	1-210	Engine dead, but warm at end of test
	2-216	Data correct, suspicious sample recounted
44	2-216	Data correct, suspicious sample recounted
45	1-194	Data correct, suspicious sample recounted
47	1-218	Data correct, suspicious sample recounted
	2-210	Filter dropped
	2-216	Data correct, suspicious sample recounted
	2-218	Engine dead at end of test
	1-236	Data correct, suspicious sample recounted
66	1-194	Filter missing, value interpolated
67	1-236	Data correct, suspicious sample recounted
68	1-236	Data correct, suspicious sample recounted

FIVE FOOT SAMPLE HEIGHTS

Run	Position	Note
13	1-240	No filter, counted backing
	1-252	Carbon on filter
	2-258	Light dust on filter
15	1-288	Filter dropped
21	2-246	Carbon on filter
35	2-264 through 2-294	Light dust on filters

TABLE 7. Summary of field and laboratory notes for the Dry Gulch experiments. Position denotes arc and azimuth location of sampler.

Run	Position	Note
2	2-1307 2-1309 2-137 2-1369	Low vacuum gauge readings; correction applied from curve of below critical flow rate vs. pressure drop.
2	7-134	Interpolated; low count-no explanation; interpolated count-20,448, original count-1484.
	8-114	Interpolated; no vacuum relief valve - replaced 1100 hrs.
	8-120	Interpolated; no membrane filter in filter holder.
	8-122	Interpolated; dead engine at 1315 hrs. - out of gas; in ravine.
	8-124	Interpolated; engine not installed.
	8-126	Interpolated; dead engine at 1315 hrs. - out of gas; in ravine.
	9-115	Interpolated; dead engine at 1325; heavy carbon deposit.
	9-123	Interpolated; low count - no explanation; interpolated count-366, original count-27.
3	7-004	Interpolated; low count - no explanation; interpolated count-28,260, original count-531.
	7-124	Interpolated; low count - no explanation; interpolated count-24,102, original count-283.
	8-104	Interpolated; heavy carbon deposit.
	8-124	Interpolated; low count - no explanation; interpolated count-38,781, original count-5294.
	8-122	Interpolated; heavy carbon deposit; in ravine.
	8-124	Interpolated; engine not installed.
4	2-117	Interpolated; low count - no explanation; interpolated count-383, original count-8.
5	8-122	Interpolated; heavy smoke deposit; in ravine.
	8-126	Interpolated; heavy carbon deposit; in ravine.
6	2-123	Interpolated; heavy carbon deposit.
7	7-118	Interpolated; dust cap not removed.
	8-110	Interpolated; no flow through filter.
	8-128	Interpolated; low count - no explanation; interpolated count-2717, original count-667.
	8-122	Interpolated; in ravine; interpolated count-2000, original count-670.
	8-124	Interpolated; in ravine; interpolated count-1200, original count-147.
	8-126	Interpolated; in ravine; interpolated count-700, original count-66.
9	1-173	Extrapolated beyond edge of grid.
	1-175	Extrapolated beyond edge of grid.
10	8-124	Interpolated; in ravine; interpolated count-1393, original count-222.
	9-100	Extrapolated beyond edge of grid.
13	8-124	Interpolated; in ravine; interpolated count-1125, original count-337.
17	7-148	Interpolated; low count - no explanation; interpolated count-2232, original count-71.
	8-122	Interpolated; heavy carbon deposit; in ravine.
	8-124	Interpolated; in ravine; interpolated count-8110, original count-2771.
	8-144	Interpolated; dead engine - gas valve not opened.
	8-146	Interpolated; dead engine - gas valve not opened.
	8-148	Interpolated; dead engine - gas valve not opened.
	9-124	Interpolated; below critical flow - bad vacuum gauge.
18	7-148	Interpolated; low count - no explanation; interpolated count-59,718, original count-1027.
	9-124	Interpolated; below critical flow - bad vacuum gauge.

TABLE 7 (contd)

Run	Position	Note
19	1-116	Interpolated; heavy dust deposit.
	1-137	Interpolated; heavy carbon deposit.
	2-099	Interpolated; behind trees; interpolated count-1231, original count-804.
	2-126	Interpolated; heavy dust deposit.
20	2-130	Interpolated; heavy carbon deposit.
	2-151	Interpolated; dead engine - out of gas; heavy carbon deposit.
	2-103	Interpolated; behind trees; interpolated count-1861, original count-518.
	2-108	Interpolated; near tree; surrounded by cyclone fences; interpolated-1287, original count-475.
21	7-148	Interpolated; low count - no explanation; interpolated count-2561, original count-108.
22	7-148	Interpolated; low count - no explanation; interpolated count-7248, original count-229.
24	7-122	Interpolated; moderate carbon deposit; interpolated count-6778, original count-1131.
27	8-129	Interpolated; no flow through filter.
	1-161	Interpolated; clean filter mistakenly brought in from field.
29	9-107	Extrapolated beyond edge of grid.
	9-108	Extrapolated beyond edge of grid.
	9-109	Extrapolated beyond edge of grid.
	2-138	Interpolated; dead engine at 1145; plugged orifice.
34	9-107	Extrapolated beyond edge of grid.
	9-108	Extrapolated beyond edge of grid.
	9-109	Extrapolated beyond edge of grid.
	7-148	Interpolated; low count - no explanation; interpolated count-18,050, original count-538.
41	9-138	Interpolated; in dense trees; interpolated count-295, original count-83.
	8-136	Interpolated; in ravine; interpolated count-3838, original count-606.
43	1-173	Extrapolated beyond edge of grid.
	1-175	Extrapolated beyond edge of grid.
	2-172	Extrapolated beyond edge of grid.
44	2-137	Interpolated; cap not removed.
45	7-182	Extrapolated beyond edge of grid.
46	2-172	Extrapolated beyond edge of grid.
49	7-122	Interpolated; low count - no explanation; interpolated count-24,228, original count-11,956.
51	2-148	Interpolated; low count - no explanation; interpolated count-6076, original count-9.
52	2-158	Interpolated; dead engine.
	2-172	Extrapolated beyond edge of grid.
	3-173	Extrapolated beyond edge of grid.
53	2-127	Interpolated; dead engine - cold at 1750.
54	1-149	Interpolated; filter not changed; found on test 58 - no good.
56	2-157	Interpolated; filter lost.
	8-112	Interpolated; dead engine.
61	9-122	Interpolated; filter lost.
73	2-149	Interpolated; dead engine - cold at 1420.
77	9-130	Interpolated; dead engine - cold, gas tank 3/4 full at 1840.
81	9-100	Interpolated; dead engine.
82	9-101	Interpolated; dead engine.
	1-147	Interpolated; low count - no explanation; interpolated count-1300, original count-58.

TABLE 7 (contd)

<u>Run</u>	<u>Position</u>	<u>Note</u>
86	9-126	Interpolated; low count - no explanation; interpolated count-880, original count-88.
87	8-118	Interpolated; low count - no explanation; interpolated count-2500, original count-8.
88	1-123	Interpolated; dead engine - warm at 1845 - restarted.
89	1-159	Interpolated; dead engine at 2145.
90	8-132	Interpolated; in ravine; interpolated count-320, original count-2.
95	1-179	Extrapolated beyond edge of grid.
	1-181	Extrapolated beyond edge of grid.
96	8-116	Interpolated; filter ruptured.
97	8-118	Interpolated; low count - no explanation; interpolated count-9700, original count-38.
	9-119	Interpolated; in ravine; interpolated count-1300, original count-431.
99	2-141	Interpolated; dead engine - cold at 2105 - restarted.
101	9-119	Interpolated; in ravine; interpolated count-1370, original count-258.
103	2-149	Interpolated; dead engine.
105	8-118	Interpolated; dead engine - bad spark plug - restarted.
106	9-096	Interpolated; dead engine - out of gas, cold at 0028.
107	7-144	Interpolated; dropped filter after test.
108	1-179	Extrapolated beyond edge of grid.
	1-181	Extrapolated beyond edge of grid.
	1-183	Extrapolated beyond edge of grid.

Acknowledgments

The authors gratefully acknowledge the careful and diligent efforts of the many people who have helped to prepare these data for publication. In particular, we wish to express our thanks to Darold Hughey and W. T. Hinds, General Electric Company, for their long hours spent with the Rankin counter and processing the raw data through the IBM 704. We are also indebted to Joan Dwyer, AFCRL, for preparation of Tables 1, 2, 4, 6, and 8 from the basic data tabulation sheets.

Air Force Cambridge Research Laboratories

1. STANDARD DEVIATIONS OF THE AZIMUTH FLUCTUATIONS

The wind direction traces on the Type M strip charts were read at 2-sec intervals on a Gerber Automatic Chart Reader, No. GDDRS-3, and were digitized on cards by Research Calculations, Inc. These data cards were used as input for an IBM 650 program to compute the standard deviations, $\sigma(\theta_g)$ of azimuth fluctuations, θ_k . Strip chart readings were made only every 2 sec because the type M vanes are relatively slow response instruments. Turbulent eddies of less than a 2-sec duration made practically no contribution to the $\sigma(\theta_g)$. It has been concluded by Hay and Pasquill¹ that the crosswind spread of particles from a continuous point source could be reliably computed from smoothed azimuth fluctuation data. They indicated that these data should be smoothed by using a running mean averaging period of approximately one quarter of the mean downwind travel time of the released particles out to a selected distance. For the diffusion prediction equations developed at a later date, however, the running mean averaging period chosen for

Ocean Breeze and Dry Gulch was 16 seconds. A description of the development of these $\sigma(\bar{\Theta}_s)$ may be found in Chapter I of Volume II.

Here, the smoothed $\sigma(\bar{\Theta}_s)$ are listed. The results using various non-overlapping averaging periods are also listed since these were easily computed in the same computer program. The variable subscript s indicates the time span, in seconds, of the variates, $(\bar{\Theta}_s)_i$, used in each $\sigma(\bar{\Theta}_s)$ computation. $s = 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 1536, 2048, 2560$.

The first 30 min of each wind direction record that was read coincided with the tracer emission period. For most of the experiments, another 18 min were read to take into account a rough indication of downwind mean travel time. Therefore, a sample size of 1440 data points was used for most of the computations for $\sigma(\bar{\Theta}_s)$.

$$\sigma(\bar{\Theta}_s) = \left\{ \frac{1}{n_s - 1} \left[\sum_{i=1}^{n_s} (\bar{\Theta}_s)_i^2 - \frac{1}{n_s} \left(\sum_{i=1}^{n_s} (\bar{\Theta}_s)_i \right)^2 \right] \right\}^{1/2} \quad (1)$$

For the nonoverlapping means,

$$(\bar{\Theta}_s)_i = \frac{2}{s} \sum_{k=(i-1)s/2+1}^{is/2} \Theta_k \quad i = 1, 2, \dots, n_s \quad (2)$$

$$\text{where } n_s = \left\lfloor \frac{N}{s/2} \right\rfloor$$

For the overlapping means,

$$(\bar{\Theta}_s)_i = \frac{2}{s} \sum_{k=i}^{is/2-1} \Theta_k \quad i = 1, 2, \dots, n_s \quad (3)$$

$$\text{where } n_s = N - s/2 + 1$$

Table I presents these standard deviations for all Ocean Breeze diffusion runs except run 76 (type M chart lost enroute). Word one of the output is an identification word. A one in Column 1 indicates the location, AMR. The next four columns are the date block: month and day. A five, six, or seven in Column 6 indicates the first, second, or third experiment, respectively, of the same day. Column 7 contains a 1 or 2; a year code. The last three columns indicate the number of minutes of recording that were read, and were programmed to establish the upper limits of n_s for the nonoverlapping smoothings as follows:

Column 8, 9, 10	Time (min)	Maximum s (sec)
038	13-17	64
098	18-26	64
889	27-34	128
989	35-43	128
099	44-48	128

The next eight to eleven ten-digit words contain the nonoverlapping means used in the longest nonoverlapping sigma computation, that is, that with the largest s . These means are rounded off to the nearest whole degree and are packed two to a word with four zeros separating each pair.

The following two lines are the nonoverlapping variance and standard deviation for each value of s . Thus, the first of these lines shows $\sigma(\theta_2)^2$, $\sigma(\theta_2)$, $\sigma(\theta_4)^2$, $\sigma(\theta_4)$, $\sigma(\theta_8)^2$, $\sigma(\theta_8)$, $\sigma(\theta_{16})^2$, $\sigma(\theta_{16})$. The $\sigma(\theta_2)$ is unsmoothed since each variate is a 2-sec reading. Both $\sigma(\theta_2)^2$ and $\sigma(\theta_2)$ are repeated at the beginning of the overlapping output that follows the nonoverlapping output.

All the sigma tabulations are in floating point format with the last two digits of each word representing the machine exponent, m . Each number is, therefore, equal to the eight-digit digitand multiplied by ten raised to the $(m-50)$ power. The decimal point of the digitand is always located immediately to the left of the extreme left digit. The final one word line of output, (found mainly in Phase II and III of the Ocean Breeze runs), is the mean wind direction, $\frac{1}{N} \sum_{i=1}^N (\theta_2)_i$, and is also in floating point.

Table 2 lists the Dry Gulch results. The data were reduced and processed in the same manner as the Ocean Breeze data. A two in Column 1 of the identification word indicates the D course at Vandenberg, and a three, the B course.

Missing data for high values of s in the Dry Gulch experiments are due to dropping of the tens position of the eight-digit digitand when the machine exponent exceeded 58. This occurred in the $\sum (\theta_8)_i^2$ when the θ_8 were large fourth quadrant values, and s was greater than 1536. Using Eq. (1), a negative result was produced, but, of course, this was set to zero in the output.

At a later date, all the Type M charts for both Ocean Breeze and Dry Gulch were reread at 10-sec intervals for the 30-min emission period. The unsmoothed sigmas, $\sigma(\theta_{10})$, were computed on a Packard Bell 250 computer using a program which also processed nondiffusion Ocean Breeze and Dry Gulch runs in the same way the diffusion runs were processed on the IBM 550.

2. AZIMUTH FREQUENCY DISTRIBUTIONS

Frequency distributions of the 2-sec and 10-sec azimuth readings were compared by constructing histograms of the 2-sec data using 10° class intervals. Frequency polygons of the 10-sec data were then superimposed on the 2-sec histograms. In each of these graphical representations, the frequency polygon conformed very closely to the corresponding histogram. These comparisons are not shown here. However, a scatter diagram of $\sigma(\theta_2)$ vs $\sigma(\theta_{10})$ is presented in Figure 1 for Ocean Breeze, and Figure 2 for Dry Gulch. For comparison purposes these data are presented in Tables 3 and 4 respectively.

3. TEMPERATURE DIFFERENCES AND WIND SPEED DATA

The ΔT 's for all Ocean Breeze runs were computed from three wiresonde temperature measurements taken at intervals of 50 ft to a height of 500 ft for each ascent and descent of the captive balloon. These temperature differences are tabulated in Table 5 in degrees centigrade. The letter m denotes missing data. No wiresonde data were available for runs 54, 60, 63, 64, 72, and 74. Therefore, ΔT 's listed for these runs were obtained from WIND System printouts.

Temperature differences for Dry Gulch experiments were initially obtained by wiresonde instruments mounted on an Atlas Gantry, and after Experiment 20, by wiresondes, for the first series of experiments. For the second and third series, measurements of temperature differences between 6 ft and 54 ft were recorded from shielded thermocouple junctions, and these, as well as the wiresondes, were used. Throughout the second series of experiments, ΔT_{54-6} 's were also obtained from Rustrak recordings of 6-junction thermopiles mounted in Beckman-Whitley aspirated shields. The ΔT 's for all the Dry Gulch experiments are found in Table 6 in degrees centigrade.

The 'gantrysonde' readings are listed under Column 1 of ΔT data where the difference was taken from 50 ft to roughly 6 feet. In Column 2 are found the readings that were estimated from rawinsonde data taken at nearby Point Arguello because no 'gantrysondes' were available for these runs. All wiresonde data available for Experiments 30B through 109B are listed in Column 3 of the ΔT data. These readings are from 50 ft to about 6 feet. The next column of the ΔT listings shows measurements recorded from the shielded thermocouple junctions erected on the B course referred to as Mod II site. The last column is a tabulation of the Rustrak recordings from the 6-junction thermopiles located near the D course source point.

The wind speed data for all Ocean Breeze and Dry Gulch experiments were read from the strip chart recordings of the Belfort Instrument Company's Type M

Figure 1. $\sigma(\theta_2)$ vs $\sigma(\theta_{10})$ for Ocean BreezeFigure 2. $\sigma(\theta_2)$ vs $\sigma(\theta_{10})$ for Dry Gulch

anemometer and are tabulated together with the ΔT 's in the aforementioned tables. These \bar{U} data are in tenths of meters per second.

4. RAWINSONDE DATA

Rawinsonde data collected from Cape Canaveral by Pan American Airways are tabulated for the three experimental phases of Ocean Breeze in Table 7. If an observation was not taken during the two hours before, during the pigment generation period, or during the 60 min following the generation shut off, then the two closest observations are given, if available. The time to the right of the data is the starting time of the experiment; the time in parentheses on the next line is that of the rawinsonde observation. No observations were available that coincided with Experiments 24, 41, 42, 43, and 44.

Values of pressure, height, temperature and relative humidity are given for significant and mandatory levels. The pressure is given in whole millibars, the height in meters above the ground, the temperature in degrees centigrade, and the relative humidity in per cent.

The values for the winds are given for the standard heights. The height is given in meters above the ground, the direction in whole degrees, and the speed in meters per second. Calm wind conditions are denoted by c.

Table 8 presents the rawinsonde observations for Dry Gulch made by the U. S. Weather Bureau's Point Arguello rawinsonde station. No observations were available for Experiments 20-B, 49-D, 50-B, and 102-D. All values are given in the same units as the Ocean Breeze observations.
